Computer Science, Eindhoven University of Technology, Eindhoven
Abstract

This document provides the main guidance for the Integration Tests (IT) during the Detailed Design (DD) phase of the IMSETY project. It describes the environment needed to perform the IT. When this environment is set up, all test cases must be executed according to their corresponding test procedures. After a test has been performed a report needs to be written.

Chapter 1

Introduction

1.1 Purpose

This document describes the plan for integration testing the developed software package against the architectural design as defined in the ADD [2]. The purpose of this integration test is to make sure that IMSETY complies with the design as described in the ADD [2]. These tests should be executed during the Detailed Design (DD) phase of the IMSETY project as described in the ESA software engineering standard [1].

1.2 Overview

Chapter 2 mentions the items to be tested together with the general criteria for the IT. A specification for each test case is given in chapter 3. The procedures for these test cases are explained in chapter 4. In chapter 5 the reports for all test cases are presented.

1.3 List of definitions

| AD       | Architectural Design |
| ADD      | Architectural Design Document |
| DD       | Detailed Design |
| ESA      | European Space Agency |
| IT       | Integration Test |
| ITP      | Integration Test Plan |
| SVVP     | Software Verification and Validation Plan |

1.4 List of references

Chapter 2

Test plan

2.1 Test items

The software to be tested is IMSETY. Information about the architectural design of this system can be found in the ADD [2].

2.2 Features to be tested

IMSETY must meet the design as stated in the ADD [2]. The integration between each defined component should be subject to a test.

2.3 Test deliverables

Before the testing starts the following items must be delivered:

- SVVP [4]
- ADD [2]
- ITP [3], chapters 1, 2, 3 and 4
- IT input data
- IMSETY software package

After completing the testing the following items must be delivered:

- IT report (ITP chapter 5)
- IT output data
- Problem reports (if necessary)

2.4 Testing tasks

Before any testing in the IT phase can take place, the following tasks need to be done:

- Designing the integration tests.
- Tracing all test cases to components.
- All integrations of components need to be covered by test cases.
CHAPTER 2. TEST PLAN

• Creation of IT input data.
• Ensuring that all environmental needs are satisfied for the IT.

When these tasks have been done an IT can be performed according to the procedures described in chapter 4.

2.5 Environmental needs

To be able to perform the IT the following resources are needed:

For the server:
• A computer running Linux with CppUnit, XML-RPC and MySQL++ installed.
• An MCC (-stub) available local or remote to the above described machine.
• An MCS (-stub) available local or remote to the above described machine.

For the client:
• A computer running Windows 2000/XP/Vista, Linux or OpenSolaris.
• Qt4 available on the local machine.

See also the constraints described in the ADD [2] in chapter 7.

2.6 Test case pass/fail criteria

Every test should describe the criteria that should be met to pass a specific test. An overall IT pass can only be achieved when all tests described in chapter 3 have been performed and passed.
Chapter 3

Test case specifications

For the test case specifications see the respective test case specifications in the automated test framework. For the client this can be found in src/client/test, for the common files (mostly the administration packages) this is src/common/test, for the server the test cases can be found in src/server/test.

All tests can be found in these folders in the files testname_i{test}.h, testname.cpp, where testname is the name found in the Test name column in the tables in the following sections.

We will however describe the various integration tests with respect to what integrations need to be carried out in the following sections. This testing will be done cumulative. This means that if two components pass an integration test they can be integrated together with other components. This implies that the test should be performed in the given order within each part, and that the Common part must precede the others.

3.1 Common

Chapter 4

Test procedures

In order to be able to automate the integration testing of IMSETY the authors of the integrated components are also responsible for writing the specific integration test belonging to the components. The integration tests need to be placed in the directories described further on in this chapter (either in the Client or the Server section). Note that testing components from the src/common directory will be carried out conform the test framework of the server.

By having the authors of the components also write the test belonging to the components, it should never occur that a component goes into the source code repository untested. This means that the author is also responsible for carrying out the tests before committing code.

Carrying out tests is different for the client and the server because at the client side we also need to be able to test the graphical user interface (GUI). Therefore we will also describe the test procedures for the client and the server separately.

4.1 Client

On the client side, for each test that needs to be run there is a .pro file in the src/client/test/ directory, along with a .cpp file which implements a specific test. These tests cannot be easily aggregated in a single test suite because of shortcomings of the Qt test framework (if we would aggregate the tests in one test suite, a crash of one test would lead to the rest of the suite not being executed). In order to overcome this we have added a shell script which runs all individual tests, as the tests won’t run from within the build system.

Note that all test names (denoted with testname) should be name_itest, as this is needed for running the batch of tests.

Individual client tests can be run by going to the src/client/test/ directory and there executing:

```
# scons testname
# ./testname
```

A batch with all tests can be run by executing src/client/test/integrationtest.sh.

4.2 Server

Carrying out unit tests for the server is a lot simpler than for the client. For carrying out server integration tests we use the CppUnit [5] test framework. Whenever we mention the server, this also applies to the common files, substituting server by common.

For each integration test that needs to be run against the server, there is a name_itest.{h, cpp} file in the src/server/test directory.

Full server tests can be run by going to the src/server or the src/server/test directory and running:
# scons integrationtest

When only a single test needs to be run this can be done by going to the `src/server/test` directory and running:

# scons name_itest
Chapter 5

Test reports

When a test report for an integration test is desired, for all components a test report can be gen-
erated from the test run. In case of the server and common files a test report is always automatically
generated respectively in the src/server/test/report or the src/common/test/report folder. For the client a test report is always written to the screen. This can be overcome by redirecting test output to src/client/test/report/testname_report.txt by using the --report option, like src/client/test/integrationtest.sh --report.

Due to lack of time during the coding phase of the project no integration tests have been automated. Integration tests have been executed manually in order to verify the integration of subsystems. However this has been done in an ad-hoc manner, such that no test reports have been written.
